

GE TRANQUELL™ Surge Arresters

Product Selection & Application Guide

Polymer/Porcelain Station & Polymer Intermediate Class Arresters
New 2013 GE AS Station Class Product Line:
IEEE®/ANSI® C62.11

Product Description

The GE TRANQUELL line of surge arrester products provide excellent protective characteristics, temporary over voltage capability, and switching surge energy withstand to power systems.

GE arresters are ideally suited for application in both indoor and outdoor situations. They are designed and manufactured in accordance with the latest revision of ANSI/IEEE C62.11.

GE Surge Protection

The performance and reliability of today's electric power system can be enhanced with the unique characteristics of GE TRANQUELL arrester products. Since introducing the world's first metal oxide arrester in 1976, offering new concepts in surge arrester design and application, GE has developed and applied metal oxide technology for a variety of traditional and special applications. GE offers an extensive line of surge arrester products. From distribution class to EHV arresters up to 612kV rating as well as high energy varistors for series capacitor applications.

Product and power systems engineers work closely to optimize product performance on the system. This tradition has made GE one of the world's leading suppliers of metal oxide arresters and specialty varistors.

Station Arresters are designed and manufactured in accordance with the latest revision of ANSI/IEEE C62.11. GE TRANQUELL polymer and porcelain arresters are designed to meet the most demanding service conditions.

The new AS series of Porcelain Station Class Arrester is our replacement for the standard product line ratings (54 kV and above).

The Intermediate Polymer Arresters remain unchanged.

Introduction

TRANQUELL arresters provide exceptional overvoltage protection of major power system equipment. Under normal system conditions, the arrester appears as a high impedance path. When a surge reaches the arrester, the arrester changes to a low impedance path and conducts only the current necessary to limit the overvoltage. As a result, TRANQUELL arresters absorb minimum energy to protect equipment insulation.

Arrester Construction

Metal Oxide Disks

The core operating component of a modern Lightning arrester is the Metal oxide varistor element. As a leader in MOV formulation and their use in a Gapless construction design, all classes of GE arresters the same quality MOV.

Classes of ANSI/IEEE C62.11 Arresters

GE TRANQUELL arresters are offered in all classes:

Porcelain and Polymer Station Class, Polymer Intermediate Class, Polymer Distribution Class and Riser Pole.

Porcelain Surge Arresters

GE TRANQUELL Porcelain surge arresters have been the industry standard for decades. Porcelain models cover Voltage ratings from 3kV to 612kV. GE TRANQUELL Porcelain EHV (Extra High Voltage) Arresters cover ratings above 420kV.

With unrivaled mechanical strength, and an altitude rating to 12,000 feet ASL (3,600 M ASL) GE TRANQUELL Porcelain models fill the most demanding applications. Tested in accordance with IEEE 693, most models meet the High Seismic Performance level.

Porcelain EHV Arrester

GE TRANQUELL EHV arresters incorporate a heat transfer system utilizing silicone-rubber material wedged between the metal oxide disk and internal porcelain wall. Heat generated in the valve element from steady state, temporary, or transient conditions is transferred through the silicone-rubber material to the porcelain housing and then dissipated to the outside environment.

GE TRANQUELL arresters are designed and tested in accordance with ANSI/IEEE C62.11 standards

Polymer Surge Arresters

GE TRANQUELL polymer surge arresters are constructed utilizing a rugged field-proven silicone alloy EPDM housing. Polymer models cover Voltage ratings from 3kV to 228kV. GE TRANQUELL polymer arresters offer exceptional electrical characteristics such as low protective levels, high energy handling capability, and improved TOV capability. The electrical performance of the polymer arresters is enhanced by its ability to easily transfer heat from the metal oxide elements to the outside environment. These light weight non-shattering design, fit both 8.75" and 10" mounting patterns.

Arrester Testing ANSI/IEEE C62.11

GE TRANQUELL arresters comply with the design tests outlined in ANSI/IEEE C62.11. At minimum the IEEE C62.11 clauses below are tested to, and met.

- Insulation Withstand
- Discharge Voltage
- Disc Accelerated Aging
- Contamination
- RIV
- High Current , Short Duration
- Transmission Line Discharge
- Duty Cycle
- Temporary Overvoltage
- Short Circuit
- Ultimate Mechanical Strength-Static
- Partial Discharge

In addition, factory tests are performed on each metal oxide disk. Long-term stability tests are conducted on each and optimized. Every disk is subjected to an impulse current of 10kA 8/20ms to measure its discharge voltage or nominal protective level. A disk strength test series, consisting of multiple transmission-line discharges, is performed to make certain that the disk has full energy capability.

Arrester Rating Selection Application Guide

The objective of arrester application is to select the lowest rated surge arrester that will have a satisfactory service life on the power system while providing adequate protection of equipment insulation. An arrester of the minimum practical rating is generally preferred because it provides the greatest margin of protection for the insulation. The use of a higher rating increases the capability of the arrester to survive on the power system, but reduces the margin of protection it provides for a specific insulation level. Thus, arrester selection must strike a balance between arrester survival and equipment protection.

Table 1 lists arrester ratings that would normally be applied on systems of various line-to-line voltages. The rating of the arrester is defined as the rms voltage at which the arrester passes the duty-cycle test as defined by the referenced standard. To decide which rating is most appropriate for a

particular application, consideration must be given to the following system stresses to which the arrester will be exposed:

- Continuous system voltage
- Temporary overvoltage
- Switching surges (frequently a consideration in systems of 345kV and above, and for capacitor banks and cable applications)
- Lightning surges

The arrester selected must have sufficient capability to meet the anticipated service requirements in all categories.

For effectively grounded neutral systems, TRANQUELL arresters with MCOV equal to the maximum line-to-neutral kV is the normal application. As an example, a 230kV system usually has a maximum line-to-line continuous voltage of 242 kV line-to-ground voltage.

¹ TRANQUELL Arresters are designed to be operated at voltages equal to or less than their continuous capability as stated in MCOV column 2.

² Based on our recommended MCOV ratings for normal system voltages, for systems with ground faults lasting no more than 30 minutes.

³ Use Extra High Voltage (EHV) 9L16GNS series; see page 14 for details.

Maximum Continuous Operating Voltage

Arresters in service are continually exposed to system operating voltage. For each arrester rating, there is a recommended limit to the magnitude of voltage which may be continuously applied. This has been termed the Maximum Continuous Operating Voltage (MCOV) of the arrester. These values meet or exceed those values contained in the referenced standard. The arrester rating must be selected such that the maximum continuous power system voltage applied to the arrester is less than, or equal to, the arrester's continuous voltage capability. Attention must be given to both the circuit connection (single phase, wye or delta) and the arrester connection (line-to-ground, line-to-line). In most cases, the arrester is connected line-to-ground and therefore must withstand line-to-ground system operating voltage. If an arrester is to be connected line-to-line, phase-to-phase voltage must be considered. In addition, attention should be given to an arrester application on the delta tertiary winding of a transformer where one corner of the delta is permanently grounded. In such circuits, the normal voltage continuously applied to the arrester will be the full phase-to-phase voltage even though the arresters are connected line-to-ground.

Temporary Overvoltage

Temporary overvoltage (TOV) can be caused by a number of system events such as line-to-ground faults, circuit backfeeding, load rejection and ferroresonance. The system configuration and operating practices should be reviewed to identify the most probable forms of temporary overvoltage which may occur at the arrester location.

The primary effect of temporary overvoltages on metal oxide arresters is increased current and power dissipation, and a rising arrester temperature. TOV figures on page 6 show the temporary overvoltage capability of GE arrester designs. This figure defines the duration and magnitude of temporary overvoltage that may be applied to the arrester before the arrester voltage must be reduced to the arresters' continuous operating voltage capability. These capabilities have been defined independent of system impedance and are therefore valid for voltages applied at the arrester location.

Service Conditions and Other Considerations

Arrester Contamination

GE TRANQUELL arresters are built in accordance with contamination tests outlined in ANSI/IEEE C62.11. More demanding tests than those outlined in the ANSI/IEEE C62.11 have shown that TRANQUELL arresters have outstanding capability to withstand the effects of very severe external contamination.

In applications where severe contamination is anticipated and extra leakage (creepage) distance is required for other station insulation, the arrester leakage distance should be reviewed. An arrester connected line-to ground needs to have a leakage distance no greater than that required for the other line to-ground insulation in the station. Extra leakage distance arrester housings are available. Manual hot washing of TRANQUELL arresters with a single stream of pressurized, de-ionized water is permissible, provided electric utility industry accepted safety precautions are observed.

Arrester Failure & Pressure Relief

In the event that the capability of a TRANQUELL arrester is exceeded, the metal oxide disks may crack or puncture. Such damage will reduce the arrester internal electrical resistance. Although this will limit the arrester's ability to survive future system conditions, it does not jeopardize the insulation protection provided by the arrester.

In the unlikely case of complete failure of the arrester, a line-to-ground arc will develop and pressure will build up inside the housing. This pressure will be safely vented to the outside and an external arc will be established provided the fault current is within the pressure relief fault current capability of the arrester. This low-voltage arc maintains equipment protection. All ratings of metal top porcelain station arresters will withstand a system available short circuit current of at least 65,000 amperes rms. symmetrical (169,000 amperes, first crest) in accordance with the test procedures outlined in ANSI/IEEEC62.11. Porcelain Pressure relief/fault current capability for all GE TRANQUELL arresters is shown in Table 3.

Once an arrester has safely vented, it no longer possesses its pressure relief/fault current capability. An arrester that has vented should be replaced immediately.

For a given application, the arrester to be selected should have a pressure relief/fault current capability greater than the maximum short- circuit current available at the intended arrester location including appropriate allowances for system growth. As with any porcelain arrester, the pressure relief apertures should be oriented away from adjacent apparatus to minimize damage to that apparatus in case of a pressure relief operation.

Ambient Temperature

Ambient temperature is an important consideration in the application of metal oxide arresters. Metal oxide materials exhibit a temperature dependent loss characteristic; the higher the ambient temperature, the higher will be the disk temperature when the arrester is operated at its continuous voltage capability.

The referenced standards indicate that the ambient temperature not exceeding 40°C is the standard service condition for arresters.

Altitude

TRANQUELL arresters are designed for altitudes up to 6,000 ft. (1800 m) above sea level, depending upon the specific model arrester. For higher altitude applications, extra clearances may be required in the design of the arrester housing. Contact GE for special design considerations and de-rating.

Mounting Considerations

TRANQUELL arresters are designed to be self-supporting for base mounting in a vertical position. However, units for other mounting arrangements are available on request. Arresters may be horizontally mounted if the cantilever loading, including arrester weight, icing, and terminal loads, does not exceed the maximum working cantilever strength. Pressure relief vents should be oriented to minimize damage to adjacent equipment by incandescent gases in the unlikely event of an arrester failure.

The rated working cantilever strengths for various arrester ratings are shown in the physical characteristics tables under the cantilever strength columns and are defined in accordance with ANSI C29.9 [8]. The defined strengths exceed the requirements for US Seismic Zone 3 (< 0.2g). For arresters installed in higher zones, seismic requirements need to be specified.

In the installation of arresters, recommended clearances between the arrester and any adjacent equipment must be observed. Failure to do so may result in unwanted flashovers and electrical overstress to internal arrester elements.

TRANQUELL arresters are designed to have a uniform voltage gradient along the length of the porcelain column. Where applicable, a grading ring is mounted on top of the arrester to establish a more uniform voltage distribution along the arrester. Clearly, if the arrester were mounted adjacent to a ground plane, this uniformity would be disturbed. To avoid such a situation, the minimum clearances to ground planes and other phase conductors must be observed.

Field Testing

In general, it is impractical to fully test an arrester in the field without high-voltage test equipment and accurate instrumentation. Instead, the arrester leakage current can be used to monitor the over-all state or condition of the arrester. For example, an abnormal leakage current measurement can be indicative of a wet surface-contaminated, or vented arrester.

Arrester leakage current can be monitored by a surge-counter leakage meter or by an oscilloscope connected directly to a surge counter test connection. Typical arrester leakage currents of station arresters operating at their continuous voltage capability and at 20°C are in the range of one-half to three milliamperes. Contamination of the arrester housing will contribute another component to the leakage current. If leakage current is to be used as an indication of arrester condition, the arrester must be clean, and the voltage and temperature must correspond to some standard test conditions, specific to each arrester location.

Arrester Selection Summary

The arrester selection process should include a review of all system stresses and service conditions expected at the arrester location. System stresses include continuous operating voltage, temporary overvoltage, and switching surges. If arresters of different ratings are required to meet these individual criteria, the highest resulting rating must be chosen. The arresters' capability for contamination, pressure relief, ambient temperature, and altitude must exceed the specified requirements.

Insulation Coordination

Once an arrester has been selected, the protection it provides to the equipment insulation can be determined. This protection is dependent on the protective characteristics of the arrester, the lightning and switching surges expected on the system, and the insulation characteristics of the protected equipment. It is quantified in terms of the protective ratio which is the ratio of the equipment insulation withstand to the arrester protective level. The objective is to meet or exceed the minimum protective ratios for the various classes of voltage surges as recommended in the application standards.

Arrester Protective Characteristics

The protective characteristic of GE TRANQUELL arresters is solely defined by the discharge voltage and is generally proportional to arrester MCOV. For any one arrester, the discharge voltage is a function of the magnitude of the arrester current and, in the impulse region, of the time to crest of the arrester current. In general, for any specific applied impulse current through the arrester, the time-to-crest for the voltage wave will be less than the time-to-crest for the current wave. Figure 2 shows the test results of a 10 kA 8/20 μ s current impulse test.

GE TRANQUELL protective characteristics have been defined for fast impulse currents with times-to-crest shorter than 8 μ s. Available data on lightning strokes and simulation studies on impulse transients within substations both indicate that arresters in service may be subjected to fast current impulse waves. To illustrate arrester protection for slower transients, the discharge voltages have been defined for standard switching surge currents.

The arrester protective characteristic is a continuous function defined over a range of discharge currents and their resultant discharge voltages. The insulation withstand of equipment on the other hand, is generally defined only at three voltage points through the use of the standard switching surge, the full wave, and the chopped wave tests. To facilitate comparison with these three withstands, three corresponding protective levels of the GE TRANQUELL arrester have been selected as indicated in Table 4, page 9.

Three protective levels are selected for coordination with the transformer insulation characteristics. They are described as follows:

- **Switching Surge Protective Level:** This is the crest discharge voltage that results when a 36/90 μ s current impulse is applied to the arrester. To define the arrester's switching surge protective level, a "switching surge coordination current" is defined for the various system voltages. These currents are: 500 amperes for maximum system line-to-line voltages to 150kV, 1000 amperes for systems 151 to 325kV, and 2000 amperes for systems above 325kV.
- **Impulse Protective Level:** This is the crest discharge voltage that results when an 8/20 μ s current impulse is applied to the arrester. The resultant crest voltages for a variety of crest currents are given in the applicable Arrester Characteristics Table. To allow coordination with transformer insulation, a specific current impulse magnitude must be selected based on the system voltage.
- **Front-of-Wave Protective Level:** This is the discharge voltage for current impulses having a faster time to crest than the 8/20 μ s current impulse. This resultant crest voltage is listed as the front-of-wave (FOW) protective level. This protective level is derived by applying a series of current wave

impulses to an arrester with varying times to crest (1, 2, 8 ms) and extending the measured voltages to 0.5 μ s in accordance with ANSI/IEEE C62.11.

In many cases, the calculated protective ratios exceed the minimum protective ratios recommended by ANSI by a considerable amount in actual power system applications.

As a specific example in protective ratio calculation, consider a 550kV BIL transformer protected by a 144kV rated GE TRANQUELL polymer station surge arrester. The three transformer insulation withstand voltages are as specified in ANSI C57.12.00[9]. The calculated ratios indicate that the arrester would provide excellent protection for the transformer insulation.

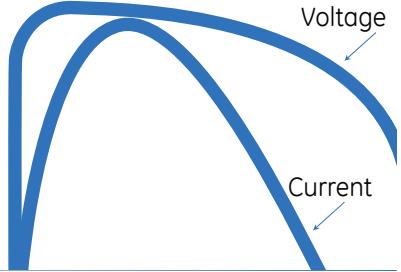

If the separation distance between the transformer and arrester is not negligible, the transformer voltage can oscillate above the arrester voltage during lightning transients, thus reducing the protective ratio. Guidance in estimating these effects can be obtained from ANSI C62.22. When making such transformer voltage estimates for shielded stations, it is suggested that the front-of-wave protective level of the arrester be used as an approximation for the arrester voltage. In decisive situations, it is suggested that digital computer studies be performed in which the arrester and substation details can be modeled.

Protective Ratios

The three-point method is usually applied for insulation coordination. In this method the protective ratios are calculated at three separate points within the volt-time domain; namely switching surge, full wave, and chopped wave regions. If the following protective ratios are met or exceeded, satisfactory insulation coordination will be achieved according to the minimum recommendations given in ANSI C62.22.

These calculated protective ratios assume negligible arrester lead length and separation distance between the arrester and the transformer.

¹ Maximum discharge voltage for a 10kA impulse current wave which produces a voltage wave cresting in 0.5 μs. This can be used for coordination where front-of-wave sparkover was formerly used.

² Based on a 500A surge of 45-μs time to crest through 88kV MCOV, and 1,000A surge of 45-μs time to crest for 98kV MCOV and higher ratings.

³ For underhung (or upside down) mounting, with eyebolt terminal on the bottom, Change letter "B" to letter "E".

* Eyebolt mounting only available for below 54kV for porcelain station class arresters

¹ Maximum discharge voltage for an impulse current wave which produces a voltage wave cresting in 0.5 μs. Discharge currents are 10kA for 2.55 - 245kV MCOV. This can be used for coordination where front-of-wave sparkover formerly was used.

² Discharge voltages are based on a 500A surge of 45 μs time to crest through 88kV MOV and 1,000A surge of 45 μs-time to crest through 180kV MCOV and 2,000A through 245kV MCOV.

¹ Maximum discharge voltage for an impulse current wave which produces a voltage wave cresting in 0.5 μs. Discharge currents are 10kA for 2.55 - 245kV MCOV. This can be used for coordination where front-of-wave sparkover formerly was used.

² Discharge voltages are based on a 500A surge of 45 μs time to crest through 88kV MOV and 1,000A surge of 45 μs-time to crest through 180kV MCOV and 2,000A through 245kV MCOV.
